

Demo Script

A two-minute demo and a five-minute presentation, with the failure plan

1. The one thing to get right

The demo has exactly one job: **show a voice note going in and a professional CV coming out.**

That moment is the product. Every second spent on architecture, stack choices or roadmap is a second not spent on the thing that makes people lean forward. Show the magic first, explain it after.

2. Two-minute video script

0:00–0:20 — The problem

"This is Um Ahmad. Eleven years as a domestic worker — cooking for large families, caring for an elderly parent, running a household. She has never had a CV. Not because she has no experience, but because every CV tool ever built assumes you can read, type, and fill in a form.

Millions of workers are locked out of formal hiring for exactly that reason. The barrier isn't skill. It's format."

On screen: a worker with a basic phone. Then a conventional CV builder — a laptop, a long form.

0:20–0:35 — The idea

"Naatiq turns a voice note into a CV."

On screen: the logo, then a WhatsApp thread opening.

0:35–1:20 — The demo (the heart of it)

Screen-record a real WhatsApp conversation. Do not narrate over it heavily — let it play.

"You send a voice note in your own dialect. Naatiq asks one simple question at a time — your name, your work, where you've worked, what you're good at, something you're proud of.

No app. No form. No typing. No reading required."

On screen: voice notes being recorded and sent. Arabic replies arriving. Then the closing message — the CV is being prepared.

"And then this arrives."

On screen: the PDF notification, then the CV opening full-screen. Hold on it. Scroll slowly through the Arabic and the English.

1:20–1:45 — Why it matters

"Every fact on that CV came from her own words. Nothing invented.

It's bilingual — Arabic so she can read and verify it herself, English because that's the language of hiring across the Gulf. One document, both audiences.

Naatiq doesn't just match people to jobs. It makes more people *matchable*."

On screen: the CV side by side, then the dashboard counter rising, then the employer portal.

1:45–2:00 — Close

"Voice in. Career out. Naatiq."

On screen: logo, WhatsApp number, join instructions.

3. Five-minute live presentation

0:00–0:45 — The problem. Um Ahmad. Eleven years, no CV. The barrier is format, not skill. Name the segments: domestic workers, drivers, tradespeople, salon technicians, kitchen staff.

0:45–2:15 — Live demo. Send a real voice note from a real phone, on screen. While the agent replies, explain what is happening underneath — transcription, one warm question at a time, structured extraction. Then the CV arrives. **Stop talking and let people look at it.**

2:15–3:00 — Show it is real. Open the dashboard: live counts, trade distribution, real CV links. Then the employer portal: real profiles, filterable by trade, CVs downloadable, and no phone numbers anywhere.

3:00–4:00 — How it works. Put up the architecture diagram. Keep it to four sentences: WhatsApp via Twilio, Groq Whisper for Arabic speech, Claude for the interview and the CV, Gotenberg for Arabic-correct PDFs, all on Supabase. Then make the two points that carry weight:

- **Arabic PDF rendering is the hard part.** Right-to-left, letters change shape by position, and most libraries get it wrong. Gotenberg wraps headless Chromium, so it inherits the browser's text engine. Solving this properly was the difference between a CV and an embarrassment.

- **Privacy is enforced in the schema.** First names come from a generated column and public roles have no permission to read full names at all. Phone numbers are never exposed. Employers request contact through Naatiq.

4:00–4:40 — Honesty and roadmap. State one real limitation before anyone asks: Arabic voice replies are built and deployed but gated behind a paid TTS plan, so the agent's side still requires reading — the literacy loop is only half closed. Then: dialect breadth, more languages, job matching, and signed CV URLs before production.

4:40–5:00 — Close. *Voice in. Career out.* Marginal cost is a few cents per CV, which is why it can reach an audience that cannot pay.

4. Questions to expect

"How do you know it isn't making things up?" The CV writer is explicitly prohibited from inventing employers, dates, skills, tools or achievements, and is permitted only three transformations: professionalise wording, fix grammar, infer an obvious job title. Below the prompt, a code-level merge falls back to the raw interview data field by field, so every line is traceable to something the worker said.

"Why WhatsApp?" Because it is already installed, already used daily, and voice notes are the native register for this audience. Any other channel reintroduces a barrier.

"What about other languages?" The architecture is language-agnostic — the prompts and the transcription language are configuration. Urdu, Hindi, Bengali, Tagalog and Amharic are the realistic next set, and are the largest untapped part of the audience.

"How does the worker know the CV is accurate?" They receive the Arabic version, in their own language, and can read or have it read to them. Editing is not yet supported — that is a known gap.

"Is this ready for production?" No, and the gaps are documented rather than hidden: private CV storage with signed URLs, Twilio signature verification, explicit consent, a deletion path, and rate limiting. The core loop is proven; the hardening is not done.

"What did you build versus configure?" Two Edge Functions, two production prompts, four migrations with a schema-level privacy model, a bilingual CV template, three front-end surfaces, and a self-hosted PDF service. The self-test diagnostic tooling found four production bugs.

5. Failure plan

Live demos fail. Have all of it ready before walking on stage.

- **Record the full happy path as video beforehand.** If anything stalls, play it. Never debug in front of an audience.
- **Have a completed CV PDF open in a tab** so the artefact can be shown even if nothing else works.
- **The dashboard already degrades gracefully** — it renders from embedded snapshot data instantly and overlays live values, so a bad network shows slightly stale numbers rather than an error.

- **Warm up Gutenberg** a few minutes before presenting; a sleeping free-tier container adds cold start latency.
- **Rejoin the Twilio sandbox from the demo phone** on the day. Join codes expire, and this is the single most likely thing to break.
- **Run one full end-to-end conversation an hour before** — it is the only real check that everything still works.
